FOR

UNITED STATES LETTERS PATENT

TITLE: PROVIDING INTEGRATED CHASSIS ANTENNA
FOR PROCESSOR-BASED DEVICES

INVENTOR: MICHAEL J. SCHAFFER

Express Mail No. EL911617266US

Date: October 22, 2001

PROVIDING INTEGRATED CHASSIS ANTENNA
FOR PROCESSOR-BASED DEVICES

Background

5 The present invention relates to the field of wireless computer networking.

10 Currently, one of the newest trends in the personal computer (PC) industry involves wireless networking. Specifically, the ability to inexpensively and reliably interconnect multiple computers, peripherals, and like devices within an office or home, without having to install an Ethernet or twisted pair backbone wiring is a strongly desired goal for office and home networking device Original Equipment Manufacture ("OEM"). To achieve this goal, a variety of wireless networking solutions have been
15 designed. These wireless computer networks typically use the radio frequency (RF) bands at 900 MHz and 2.4 GHz that were provided for this type of application.

20 Typical solutions for desktop computers are comprised of a Personal Computer ("PC") card that plugs into a computer and an antenna that connects to the PC card. The antenna is then mounted onto the outside of the computer case or other convenient external object. For example, the antenna may incorporate a magnetic mount that holds the antenna onto the top of the computer chassis.

Alternatively, an antenna may be attached to the computer chassis with an adhesive tape.

However, these systems suffer from at least two deficiencies. First, they are expensive to make. Having
5 to make a separate PC card for the network increases the unit cost relative to a computer with all the circuits on the main board. Given the heavy cost constraints, all PC OEMs have, a single main board solution is highly preferable. The second deficiency relates to the antenna.
10 An external antenna is expensive to supply to the end user. These antennae are typically manufactured by companies specializing in such devices and must be purchased by the computer OEM and packaged with the computer. This increases the logistical issues and costs for the OEM.

15 While putting the wireless networking components on the main board reduces the unit cost, it creates the problem of connecting an antenna to those network components. Also, as the chassis provides a shielding function "Faraday Cage" to suppress electro-magnetic
20 interference ("EMI"), any cable passing through it will provide an unwanted outlet for radiation that can cause EMI. Even if the cable is shielded, such as a coaxial antenna cable, and connected to electrical ground at the main board, the impedance of the shield is such that it can
25 still act as an effective radiator for signals generated inside the computer. Such radiation may violate the strict

radiation limits imposed by the FCC on PC OEMs and prevent the computer from being sold.

There exists therefore a need for a cost effective antenna system that connects to a wireless network device
5 internal to a computer.

Brief Description of the Drawings

Figure 1 is a side elevational view of one embodiment of the present invention;

Figure 2 is a sectional view of an integrated antenna
10 according to one embodiment of the present invention;

Figures 3a-3c are side elevational views of one embodiment of the present invention;

Figures 4a-4b are side elevational views of two embodiments of the integrated antenna;

Figure 5 is a side elevational view of an integrated
15 antenna incorporating a center conductor retention feature according to another embodiment of the present invention; and

Figure 6 is a perspective view of a wireless computer
20 network incorporating a computer utilizing an integrated antenna according to one embodiment of the present invention.

Detailed Description

In one embodiment, the antenna 103, shown in Figure 1,
25 is integrated into the chassis by being formed out of the

surface 105 of the chassis 101. The left 106, right 107,
and top 109 of the antenna 103 may be released from the
surface 105 while a bottom edge 111 may remain attached to
the surface 105. The antenna 103 may be bent away from the
5 surface 105 of the chassis 101 along the bottom edge 111.
The vertical section 113 may then be bent upward from the
base section 115 with one possible configuration being a
vertical section 113 generally coplanar with the surface
105 of the chassis 101.

10 The resultant spacing of the vertical section 113 from
the surface 105 may be sufficient to provide radio
frequency isolation of the vertical section 113 and the
chassis 101 at approximately the desired frequency band of
operation of the antenna 103. In operation, a coaxial
15 cable 211 (shown in Figure 2) may be connected between the
feed point 117 of the antenna 103 and a wireless device
such as a modem that may be contained within the computer
chassis 101. Of course in other embodiments, the antenna
design may be modified such that the antenna 103 is rotated
20 from a vertical orientation. For example, the antenna 103
may be rotated such that the vertical section 113 is at an
angle that may be 45 degrees, to the base of the chassis.
However, it is generally advantageous to have all antenna
polarizations similar in a wireless network.

25 Referring to Figure 2, in one embodiment, the antenna
103 may be coupled by a coaxial cable 211 to a wireless

device 223, as one example, a wireless modem that may be located on a main board 225. In one example, the antenna 103 may be coupled to the wireless device by directly soldering the coaxial cable 211 conductors 213 and 227 to the wireless device 223. In another example, a circuit connector may be utilized to connect the coaxial cable to the wireless device 223. The center conductor 213 of the coaxial cable 211 is coupled to the feed point 117 of the antenna 103.

In one embodiment, the coaxial cable 211 shield conductor 227 may be coupled to a front edge 217 of the chassis 101 by a mechanical fastener 219. The mechanical fastener 219 may be any suitable device such as a screw or clip, as two examples, that may provide a sufficiently low impedance contact between the shield and the chassis front edge 217. Using a low impedance contact between the chassis 101 and coaxial shield 227 as the coaxial cable 211 exits the chassis 101 may reduce the unintended radiation of signals internal to the chassis 101 by the coaxial shield 227. Therefore the shielding effect of the chassis 101 may be retained.

In some embodiments, the antenna 103 may be designed such that it is useful over approximately the particular frequencies utilized by the wireless device 223. Typical wireless computer networks may use either the radio frequency (RF) bands at 900 MHz or 2.4 GHz. Therefore the

antenna 103 may be designed to be approximately resonant over at least one of those frequency bands in some embodiments. General information on antenna theory and wave propagation can be obtained from the book "Antenna Theory, Analysis and Design," by Constantine A. Balanis, published by John Wiley & Sons.

In some embodiments, the wireless device 223 may provide the antenna 103 with an appropriate Radio Frequency ("RF") signal through the coaxial cable 211. RF signals from the wireless device 223 may flow through the coaxial cable 211 to the antenna 103 causing the antenna to radiate RF energy 221. Other wireless devices that may be part of a wireless network may receive this RF energy 221.

Figure 3A-3C illustrate one example of manufacturing the antenna 103. In Figure 3A, the left 106, right 107 and top 109 of the antenna 103 may be released from the surface 105 of the chassis 101. This may be referred to as a "blanking" process where the antenna pattern is blanked out of the chassis into a "blank form". In Figure 3B, the antenna 103 may be bent away from the surface 105. In Figure 3C, the vertical section 113 of the antenna 103 may be bent generally coplanar with the surface 105 which may leave the bottom edge 111 attached to the surface 105. In some embodiments, the antenna 103 may be released and formed by a punch and die. In other embodiments, progressive dies may perform the forming. In still other

embodiments, the antenna 103 may be formed by cutting and bending.

Figure 4A illustrates another method of manufacturing the antenna 103. In this example, perforations 402 may be
5 formed along bend lines 401 and 403. The blank form 405 may then be bent to form the antenna 103.

In another embodiment illustrated in Figure 4B, the metal blank 405 may have score lines 407 and 409 that may serve to form bend lines. The blank form 405 may then be
10 bent to form the antenna 103.

The preceding methods of manufacture are illustrative of a few of the many methods that may be utilized to manufacture the antenna 103.

Figure 5 illustrates an additional embodiment where
15 the antenna 103 may be formed with a coaxial cable center conductor retention feature 513. This retention feature 513 may be formed by making a slot 515 at the antenna 103 feed point 117. In operation, a coaxial cable 211 (shown in Figure 2) may connect the feed point 117 of the antenna
20 103 to a wireless device 223 that may be mounted within the computer chassis 101. The slot 515 may hold the center conductor 213 of the coaxial cable. In some embodiments, the center conductor may then be soldered to the antenna feed point 517 if desired.

25 Figure 6 illustrates one of many possible embodiments of a wireless networking system 601. This system may

include a plurality of computers 603, 605 and 607. In some
embodiments, at least one of the computers 607 incorporates
an integrated antenna 103. The antenna 103 enables a
wireless device (shown in Figure 2) internal to the
5 computer 607 to communicate with other devices that may be
part of the network system 601. While this system 601
illustrates a network of computers, other wirelessly
networked devices such as printers, network monitors, hubs,
switches and the like may send data to, or receive data
10 from the computer 607.

In many of the above described embodiments, a direct
coupling may be made to the antenna feed point by a center
conductor of a coaxial cable. However, many other method
of feeding RF energy to the antenna may also be used. As
15 an additional example, a shunt feed system may be utilized
that may not use a direct coupling between the antenna feed
point and the center conductor of the coaxial cable.

As used herein, "integrated" or "integrating" means to
form or forming from material that forms a chassis and
20 remaining contiguous, in part, with the chassis. Also, the
above illustrated embodiments are just some of the many
possible embodiments of the invention. For example, in
other embodiments, the invention may be utilized for
wireless network hubs or switches. In yet other
25 embodiments, the invention may be utilized for wireless
phones.

While the present invention has been described with respect to a limited number of embodiments, those skilled in the art will appreciate numerous modifications and variations therefrom. It is intended that the appended
5 claims cover all such modifications and variations as fall within the true spirit and scope of this present invention.
